

IS IT A MIRACLE THAT HUMANS EXIST AT ALL?

2020

First, it's only due to our very small and finite view of the Universe that we even ask such questions. What we see on a day-to-day basis is relatively easy for us to quantify. For example, if I asked how many bricks were in the wall of a house, you could estimate the size of the wall and consider the dimensions of bricks to provide a reasonable *ballpark* approximation.

But at Universe-scale, while many such estimations are still possible, it requires leaving the bricks behind and being willing to accept an entirely new way of perceiving one's environment:

Instead of your environment being finite, it is now infinite.
Instead of your environment being largely conducive to human life, it is now wildly antagonistic to it.
Instead of time proceeding at a fixed pace, time is now a variable that can be manipulated.

Focusing on the Universe-scale view, let's view the question with fresh eyes. What do we make of the fact that conscious life exists? I'm going

to respond to that question conditionally because I believe that this condition will be acceptable to you:

Consciousness is the substrate upon which the Universe is constructed, and that consciousness is not of a fundamentally different nature from our own.

If we can accept that assertion, then everything else is just a matter of fractal mathematics.⁷⁰ From the monkey-scale point of view, we can observe this fractal function in the way that patterns are repeated at each scale of manifestation: atomic, physical, and cosmological. For example, compare the classic particle model of the atom with a solar system. That's not to say that the notion of fractals literally governs the behavior of the Universe, but the Universe has been observed to behave in a manner that is comparable.

But consciousness isn't the only ingredient required to make humans. There are very specific physical conditions that must exist for hominids to evolve on a planet. This is referred to in astronomy as "The Habitable Zone" within a solar system, which is primarily defined by its distance from its sun. Earth is obviously within the habitable zone for this solar system. Many solar systems have no planets within their habitable zone, but millions do. Therefore, the physical preconditions for life are very likely to exist within a large number of solar systems.

So now, given a Universe of infinite size, how likely would it be for the Universal consciousness to form little copies of itself wherever conditions permit? *It's all but inevitable.*

⁷⁰ A crude example of a fractal would be a mathematical function that, when graphed, is comprised of many instances of itself with infinite recursion (think Inception).
