

**GET YOUR VERY OWN PET HUMANS FOR
ONLY 400 DRACMAS WHILE SUPPLIES
LAST!**

2024

Humans are some of the most interesting pets you can choose to own. However, it's imperative that proper care be taken to ensure that they remain within their enclosure. Humans are extremely curious animals and will test the limits of any enclosure you put them in. So for their safety, we strongly advise using a Universe-class enclosure to ensure that they remain properly contained at all times.

I know what you're thinking. "A Universe enclosure?! Does it have to be that large? I was thinking that a Galaxy-class enclosure would surely be adequate. I've heard of humans being grown in enclosures as small as a Solar-class before."

We have seen time and time again that humans cannot be contained by a simple Solar-class enclosure. Do not underestimate the curiosity and ingenuity of those little guys. The same intelligence that gives rise to the complex social structures that are so fascinating to observe also leads to them developing devices that they can use to easily escape a Solar-class enclosure. This is why, as a matter of ethics, we refuse to sell human seed colonies to anyone planning to deploy them into such an inadequate container.

Admittedly, the Galaxy-class enclosures do quite a good job of keeping humans contained for many years and for some time, we would agree to sell seed colonies to purchasers using these enclosures. But again, experience has shown that, eventually, they will breach the perimeter of even this mighty enclosure. While we understand the allure of being able to display a human colony in a corner of your visitation space to easily show off to guests, it simply isn't viable over the long term.

Note that transplanting humans is too traumatic for them to survive. To date, there have been no known cases of humans being successfully transplanted from a starting enclosure to a larger enclosure later in their evolution. The problem is that we do not possess any tool delicate enough to preserve the microscopic band of atmosphere at the surface of the planets they inhabit. Without that extremely fragile band of nitrogen and oxygen, a human colony numbering in the billions will be completely decimated in the blink of an eye!

So for these reasons, we can only in good conscience sell our high-quality human seed colonies to purchasers who can demonstrate that they own and are prepared to deploy their human colony into a Universe-class enclosure. For most owners, that means dedicating an entire spatial unit to house this dominant species.

But keep in mind that despite humans' reputation for being unable to

Severin Aequus

evolve peacefully alongside any other animal species, we have found exceptions to this rule. You can deploy humans alongside any other mammals that they are capable of domesticating as either a food source, labor-producing animals, or even for the humans to keep as their own pets! Now tell me that concept isn't as cute as a horseshoe nebula!

Speaking of nebulas, one great thing about a Universe-class enclosure is that you get to observe star formations and intersecting galaxy clusters. So there are plenty of easily viewable and colorful activities to enjoy without having to peer through a microscope to see the action.

In my personal colony, I became somewhat concerned when I realized that the rather unremarkable galaxy I had just deployed my seed colony into was directly in the path of another smaller galaxy [ref: Sagittarius Dwarf Spheroidal Galaxy]. Having seen galactic mergers go badly before, I wished my little guys the best. But as you know, there was nothing I could do but watch once it was all put into motion. I am proud to say that my colony is completely unaffected by the merger. To my knowledge, at least, they appear to be utterly unaware that they are taking part in a galactic merger at all! I think I lucked out because the merger is taking place on the far side of their galaxy from the solar system where I deployed them.

As a reminder of why seed colony placement is so important and how difficult Universal anomalies are to predict, as soon as I deployed my colony, I noticed that they are also on a collision course with another smaller galaxy that will take place right in their backyard [ref: Canis Major Dwarf Galaxy]. But as you know, the odds of that disrupting life in my colony are minuscule, thanks to the relatively vast distances between stars. But in just a few billion years, they're going to impact a galaxy twice their size [ref: Andromeda Galaxy]! As long as they have inhabited planets in multiple solar systems by that time, I'm confident

they'll survive.

It really is non-stop excitement with a human colony in a Universe-class enclosure! They may look boring at first, but give them a few weeks to evolve and you'll have a vibrant galactic community before you know it.

In the interest of full disclosure, we have received numerous reports of human seed colonies failing to reach the galactic stage in their evolution. Most commonly, this is due to suicide. Basically, the humans become factionalized, and if they can't resolve themselves into one coherent social structure by the time they discover the essential mechanisms of space travel, then they will almost always use those same mechanisms to create weapons that the factions will use to their mutual destruction.

While it may appear, superficially, like a crescendo of stupidity, we urge you to bear in mind that in some distant and abstract way, humans are a reflection of us. If that were not so, then there would be no interest in creating seed colonies at all. So even in their abject failures, they can offer us lessons to reflect upon. And truly, there can be no greater gift than that [hint: This statement is worthy of deep reflection / meditation].
